

■ DIFFERENCES BETWEEN CAN AND LIN

1. General

- The protocols, which are the rules for establishing data communication, differ between the CAN and LIN. If the ECUs in the networks use different frameworks for their data, such as communication speed, communication wire, and signals, they will be unable to understand each other. Therefore, protocols (rules) must be established among them.
- Compared to the LIN, the CAN features high-speed data transmission. Therefore, the CAN is able to transmit larger amounts of data faster than other protocols. This feature makes it possible to transmit data accurately in the power train and chassis control system, which requires large amounts of data to be transmitted in short periods of time.

Protocol	CAN (ISO Standard)	LIN (LIN Consortium)
Communication Speed	500 kbps*/HS-CAN 250 kbps*/MS-CAN (Max. 1 Mbps*)	9.6 kbps* (Max. 20 kbps*)
Communication Wire	Twisted-pair Wire	AV Single Wire
Drive Type	Differential Voltage Drive	Single Wire Voltage Drive
Data Length	1-8 Byte (Variable)	2, 4, 8 Byte (Variable)

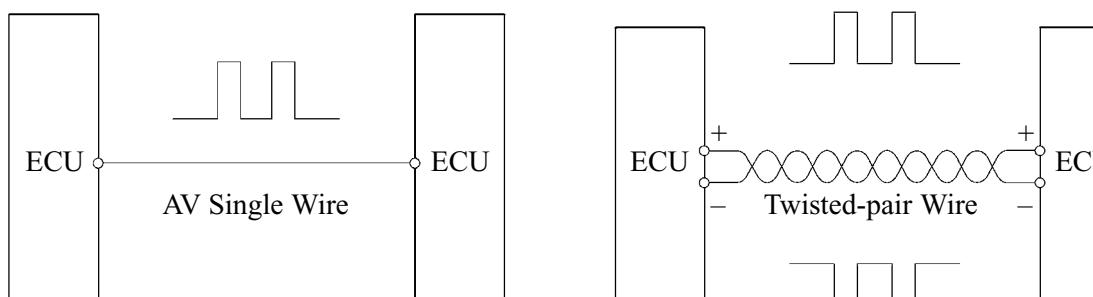

*: bps: Abbreviation for “Bits Per Second”, indicating the number of bits that can be transmitted per second.

2. Communication Wire

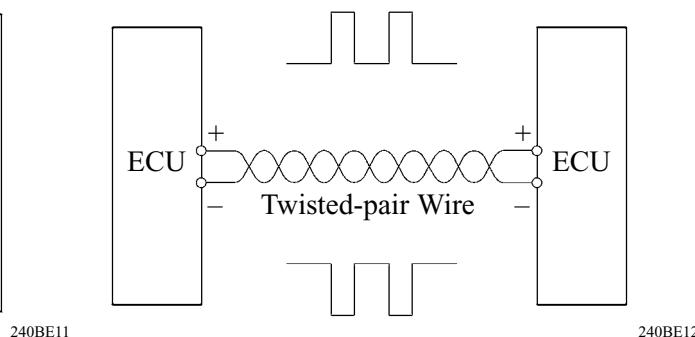

BE

A twisted-pair wire is used for CAN communication. A single, AV (Automobile Vinyl) wire is used for LIN communication.

Communication Wire	Outline
 241BE168	This communication wire is a pair of twisted lines. Communication is driven by applying different voltages to the two lines in order to send a single signal. This system, which is called a “Differential Voltage Drive”, reduces noise.
 240BE09	This is a lightweight single communication wire that consists of a single core line surrounded by insulation. Voltage is applied to this line in order to drive communication, and this system is called a “Single Wire Voltage Drive”.

Single Wire Voltage Drive

Differential Voltage Drive
